Abstract.

1 Introduction

Increasingly new technologies are used to assist humans in their daily life. For example, a robot companion for isolated elder. One condition for a successful application of these technologies is the ability to interact easily with users. Therefore, these technologies were allowed with conversational skills [8].

In the beginning, conversations with users were task centered (gives directives, ask for information to achieve tasks, etc ...) and the social aspect of dialogue was completely neglected for a long time. However, several researchers proved that social aspect cannot be ignored during the dialogue since the dialogue is social by definition [4]. Moreover, it has been found that users prefer to interact with conversational agents which have social skills [5] and these skills allow the agent to build a long term relationship with the user [2].

Social conversational agents have in addition to their usual task goals, social goals to achieve. Indeed, achieving social goals may contribute to achieve task goals [1]. For example, to achieve the task *"remind the user take his medicine"*, the agent would first achieve the social goal to *"put the user in good mood"*.

In this paper, we will discuss the impact of interpersonal relationship in the strategy of the agent during the dialogue. The mental representation of social relationship is crucial for social intelligence [3]. Therefore, depending on the interpersonal relationship that the agent will build with the user during the dialogue, it will affect its strategy to achieve its social (and task) goals. The way that we discuss with a person that we newly meet is different from a dialogue with a close friend or a supervisor.

For this paper we will focus on one single dimension of social relationship which is *dominance*. Our interest is to study how the relation of dominance can affect agent decisions during dialogue and the evolution of its strategy and behavior specially when it comes to talk about preferences and negotiate about them with the user. Moreover, as relationship is dynamic and can progress during dialogue, the agent has to adapt its strategy to the observable changes. Let's take an example of an elder who has dietary restrictions and wants to order diner. The agent knows that the elder hates this dietary restrictions. Thus, the agent defines as goal to make the user respect this food preference. Depending on its relationship with the user, the agent will adopt a specific strategy (food suggestions, linguistic style, ask for user preferences etc..) to find a type of food that the user appreciates and respects the user's diet.

2.1 Interpersonal relationship

Social relationship and its effects on behavior lies at the heart of social science. It was proved that understanding interpersonal relationship is crucial for social cognition [7]. Most of the literature that get interested in the conceptual analysis of interpersonal relationship have agreed that the essence of relationship appears in the nature of interaction that occurs between relationship partners. Moreover, social relationship is a dynamic system that may develop and change continuously over interactions [7, 9]. Communication between relationship partner will grow in stages from the initial interaction where partners share superficial information to a more deeper relationship where partners can share more personal information. Therefore, the social relationship of partners affects their behavior and their strategy of dialogue.

2.2 Representation of interpersonal relationship

The aim of this section is to relate the work of N.HASLAM who get interested on the mental representation of social relationship. In summary, there are three different representation in the literature.

The first is the dimensional representation. It is the most common representation that consists on represent relationships in a dimensional circle (c.f wiggins model). Therefore, any relationship can be situated and valued in this *continuous* dimensional space.

The second representation is the lawful representation. Laws are defined in the same circle's dimension of affiliation and control. The main difference with the dimensional representation is that laws try to make discrete prediction about the other behavior. For each behavior, complementarity and symmetry make discontinuous prediction about the the other interact behavior.

Finally, categorical representation make a discrete prediction on which kind of social relationship are well performed. In addition the categorical representation focus only on local prediction (prediction in a small region within a dimensional scheme).

| Dimensions | Laws | Categories |
|------------|---------------|---------------|
| Continuous | discontinuous | discontinuous |
| Local | Global | Local |

2.3 Dimensions of interpersonal relationship

The definition of dimensions was widely studied under different labels. However, we distinguish four dimensions that are always used for the representation of interpersonal relationship.

Dominance and power Scholars from different fields converge to define power as the ability to influence the other behavior [9]. Power may be latent (Komter, 1989), which is in contrast with the definition of dominance which is inevitably

manifest (Dunbar, 2004). It is an asymmetric variable in which one interactant's assertion of control is met by acquiescence from another (Rogers-Millar & Millar, 1979).

Familiarity In Svennevig's relational model [9], the definition of familiarity is based on social penetration theory (Berscheid and Reis, 1998) which describe the grades of relationship evolution through mutual exchange of information both in depth (superficial information to personal and intimate information) and breadth (from narrow to a broad range of personal topic).

Affect This dimension represents the degree of liking that have one interact for the other. This dimension allows interactants to create personal attachment and improve the relationship of interactants [6]

Solidarity The solidarity dimension is in the opposite of power dimension. It is a symmetrical dimension where two individuals share equal obligations and rights [9]. It is identified as like-mindedness [2] where interactants have the same behaviors and share for example the same preferences.

2.4 Dialogue acts and dialogue strategies

Propose/ Ask: One of the behaviors that come up during the experiment is that depending on the role of individual in relationship, he will introduce a discussion on preference in a particular way. For example, a powerful person will explicitly talk about its preference. In the contrast a submissive person or individual that shares affect will ask the other if he shares this preference.

Accept/ Reject: For these acts, it is still unclear how to model them. Depending on the relationship the Accept/Reject formulation will change. The interest of these acts is the way that can reflect the strategy depending on the relationship. Therefore, I think that this act should be adapted to the relationship. For example the propose act is more a dominant "behavior" and ask is a submissive" behavior.
